

Until now, we've only used React via the CDN (ie. the http links in our .html file). But [React can be installed as a dependency via Terminal](#), and included in your package.json file.

Using React as a dependency is a more advanced way of including React into your project, and is likely the default setup for most professional devs. My advice, if you're working on a super small practice project the CDN is probably fine, and then when you're on a team or building up a site include React as a dependency.

1. Install React

Note: for this project use the @15.4.2 (aka. the version number) in order to ensure your version matches up with mine. But on new projects outside of this course you can omit the version number.

```
$ npm install --save react@15.4.2 react-dom@15.4.2
```

2. Install all of your dependencies

```
$ npm install
```

3. Run the server

```
$ npm run serve
```
